Secret-Key Agreement with Public Discussion subject to an Amplitude Constraint

Marwen Zorgui, *Student Member, IEEE*, Zouheir Rezki, *Member, IEEE*, Basel Alomair, *Member, IEEE* and Mohamed-Slim Alouini, *Fellow, IEEE*

Abstract—This paper considers the problem of secret-key agreement with public discussion subject to a peak power constraint A on the channel input. The optimal input distribution is proved to be discrete with finite support. To overcome the computationally heavy search for the optimal discrete distribution, several suboptimal schemes are proposed and shown numerically to perform close to the capacity. Moreover, lower and upper bounds for the secret-key capacity are provided and used to prove that the secret-key capacity converges for asymptotic high values of A , to the secret-key capacity with an average power constraint A^2 . Finally, when the amplitude constraint A is small ($A \rightarrow 0$), the secret-key capacity is proved to be asymptotically equal to the capacity of the legitimate user with an amplitude constraint A and no secrecy constraint.

I. INTRODUCTION

This work considers the channel-type model with wiretapper for secret-key agreement (CW model) [1]–[3] which consists of a transmitter, a legitimate receiver and an eavesdropper. An authenticated and noise-free public channel is made available to the legitimate users, over which they can exchange an arbitrary number of public messages that are assumed to be perfectly observed by the eavesdropper. In this model, the objective of the legitimate users is to agree on a sequence of bits that should be kept secure from the eavesdropper. In [1], the authors established the single-letter capacity expression of the CW model for discrete channel input. Under continuous channel input and an average power constraint, the secret-key capacity is shown to be achieved by a Gaussian input with full power [3]. In this work, the capacity of the CW model subject to a peak amplitude constraint on the input is studied. The motivation behind this work is twofold. First, determining the capacity of a communication channel subject to various input constraints is a classical problem of information theory. Second, the need for incorporating an amplitude constraint is dictated by the fact that several practical communication systems are subject to a peak-power constraint or/and an average power constraint. For instance, in visible light communications, and for safety reasons, the modulating signal must satisfy an amplitude constraint, rather than a conventional average power constraint.

The problem of finding capacity-achieving distributions with an amplitude constraint has been addressed for several

channel models. In [4], Smith studied the capacity of the scalar Gaussian channel subject to both a peak power constraint and an average power constraint. The capacity-achieving distribution, rather surprisingly, was shown to be discrete, with a finite number of probability mass points. Following the same approach, several works such in [5]–[7] showed that the optimal capacity-achieving distributions are also discrete for various channel models. In [8], the authors established closed-form lower and upper bounds on the secrecy capacity of the single input single output wiretap channel with amplitude constraint. In [9], the authors considered the Gaussian wiretap channel with an amplitude constraint on the channel input. The entire rate-equivocation region of such channel was shown to be achieved by discrete input distribution with finite support.

In this paper, the capacity-achieving input distribution for the Gaussian CW model is proved to be also discrete with finite support. The result is obtained by first transforming the secret-key channel model into an equivalent Gaussian wiretap channel with better noise statistics at the legitimate receiver, and then using the fact that the optimal distribution of the Gaussian wiretap channel is discrete. The capacity-achieving probability distribution has to be computed numerically relying on a necessary and sufficient Karush-Kuhn-Tucker (KKT) optimality condition. To circumvent the numerical complexity associated with finding the capacity-achieving input distribution, suboptimal schemes are proposed and shown numerically to perform close to the capacity. Finally, lower and upper bounds for the secret-key capacity are derived. Based on these bounds, the behavior of the secret-key capacity for asymptotic high and low values of A is characterized. For instance, the secret-key capacity with an amplitude constraint converges for asymptotic high values of A , to the secret-key capacity with an average power constraint A^2 . When the amplitude constraint A is small ($A \rightarrow 0$), the secret-key capacity is asymptotically equal to the capacity of the legitimate user with an amplitude constraint A and no secrecy constraint.

II. SYSTEM MODEL

The Gaussian CW model for secret-key agreement [1] is defined by

$$\begin{aligned} Y_i &= X_i + N_{D_i}, & i &= 1 \dots n \\ Z_i &= X_i + N_{E_i}, & i &= 1 \dots n, \end{aligned} \quad (1)$$

where n is the number of channel uses. X_i , Y_i and Z_i denote the channel input, the legitimate receiver's observation, and the eavesdropper's observation, respectively. N_{D_i} and N_{E_i} are independent and identically distributed zero-mean Gaussian random variables with variances σ_D^2 and σ_E^2 , respectively. The channel input X_i is assumed to have an amplitude constraint

$$|X_i| \leq A, \quad i = 1, \dots, n. \quad (2)$$

A single-letter characterization of the secret-key capacity of the CW model with conditional probability distribution function (PDF) $p(y, z|x) = p(y|x)p(z|x)$ is established in [1] for the case of discrete channel alphabets. Following the extension to continuous channel alphabets with input average power constraint [3, Theorem 1], the secret-key capacity with a peak amplitude constraint can be expressed in a single-letter form as follows.

Lemma 1. The secret-key capacity of the CW model (X, Y, Z) with conditional PDF $p(y, z|x) = p(y|x)p(z|x)$ and a peak amplitude constraint is given by

$$C_k = \sup_{F_X \in \Omega} [\mathbb{I}(X; Y) - \mathbb{I}(Y; Z)] = \sup_{F_X \in \Omega} \mathbb{I}(X; Y|Z), \quad (3)$$

where the supremum is over all input probability distributions F_X in $\Omega \triangleq \{F_X : \int_{-A}^A dF_X(x) = 1\}$.

The secret-key capacity can be further expressed as

$$C_k = \sup_{F_X \in \Omega} [\mathbb{I}(X; Y, Z) - \mathbb{I}(X; Z)]. \quad (4)$$

In the sequel, the input distribution achieving the secret-key capacity is characterized.

III. SECRET-KEY CAPACITY

The capacity-achieving probability distribution is discrete with a finite number of probability mass points. This is formalized in the following theorem.

Theorem 1. Let F_0 be a solution to (3). Then, the support set of F_0 , $\mathcal{S}_{F_0}$, is a finite set of points.

Proof: From (4), the secret-key rate $\mathbb{I}(X; Y, Z) - \mathbb{I}(X; Z)$ is equivalent to a secrecy rate in which the destination is provided with the eavesdropper observation. Using the fact that a sufficient statistic to decode X reliably from (Y, Z) is $\frac{Y}{\sigma_D^2} + \frac{Z}{\sigma_E^2}$, along with the fact that a sufficient statistic preserves the mutual information, and after some derivations, it follows

$$\mathbb{I}(X; Y, Z) = \mathbb{I}(X; \frac{Y}{\sigma_D^2} + \frac{Z}{\sigma_E^2}) = \mathbb{I}(X; X + N_{eq}), \quad (5)$$

where N_{eq} is an equivalent Gaussian noise with variance given by

$$\text{var}(N_{eq}) = \frac{1}{\frac{1}{\sigma_D^2} + \frac{1}{\sigma_E^2}} \triangleq \sigma_{DE}^2. \quad (6)$$

This implies that the secret-key model is equivalent to a Gaussian wiretap channel with the legitimate receiver having a better noise variance given by (6). Since $\text{var}(N_{eq}) < \sigma_E^2$, the eavesdropper's channel is a stochastically degraded channel. Therefore, the optimization problem is equivalent to a Gaussian wiretap channel with an amplitude constraint problem, for which the existence of a capacity-achieving distribution and its discreteness follow along similar lines as in [9, Proof of Corollary 1]. ■

The secret-key capacity-achieving distribution can be found via a classical search algorithm as in [4]. Briefly, at each step, the number of mass points is increased by unity and the optimal input distribution for the current number of mass points is determined numerically. The process is repeated until the KKT conditions given by [9, Equations 20 and 21] are satisfied. However, such an optimization is computationally hungry, especially as the value of A increases. This motivates the search for suboptimal, but efficient schemes that

circumvent the complexity of finding the capacity-achieving distribution.

IV. SUBOPTIMAL INPUT DISTRIBUTIONS AND BOUNDS

For each of the following schemes, the secret-key rate is evaluated using a unified approach. Following the proof of Theorem 1, the secret-key channel is transformed into an equivalent Gaussian wiretap channel. Starting from (4) and using (6), the secret-key rate can be expressed as

$$\begin{aligned} \mathbb{I}(X; Y, Z) - \mathbb{I}(X; Z) &= \mathbb{I}(X, X + N_{eq}) - \mathbb{I}(X; X + N_E) \\ &= h(X + N_{eq}) - h(X + N_E) + \frac{1}{2} \log\left(\frac{\sigma_E^2}{\sigma_{DE}^2}\right). \end{aligned} \quad (7)$$

Thus, in order to evaluate the secret-key rate, one only needs to evaluate the PDF of a generic random variable $Y = X + N$ where N is an independent Gaussian noise and X follows a specific distribution that satisfies the peak constraint (2).

A. Suboptimal input distributions

One may consider suboptimal discrete input distributions such as maxentropic distributions considered in [10]. Maxentropic distributions are probability distributions over a fixed number K of equally spaced mass points that maximize the entropy of all admissible discrete distributions. In the current setting, maxentropic distributions are simply uniform distributions over the equally spaced mass points. One can then optimize over the number of mass points K to achieve better performance.

The continuous uniform distribution maximizes the entropy of the input subject to an amplitude constraint. In order to evaluate the secret-key rate achieved by a uniform input distribution, one needs to evaluate the PDF of a random variable $T = X + N$ where N is an independent Gaussian noise and $X \sim \mathcal{U}(-A, A)$ is uniformly distributed over $[-A, A]$. Using the convolution formula of the sum of independent random variables, one obtains the PDF of T , $p_T(t)$

$$p_T(t) = \frac{1}{2A} \left[\mathcal{Q}\left(\frac{-A-t}{\sigma}\right) - \mathcal{Q}\left(\frac{A-t}{\sigma}\right) \right], \quad (8)$$

where $\mathcal{Q}$ denotes the Q-function defined as $\mathcal{Q}(x) = \frac{1}{\sqrt{2\pi}} \int_x^{+\infty} \exp(-\frac{u^2}{2}) du$.

In case of an average power constraint only, the optimal input distribution is Gaussian. This suggests considering a truncated Gaussian input distributions, denoted as $\mathcal{N}_A(0, \sigma_x^2)$ [11]. The PDF of the truncated Gaussian is given as

$$p_X(x) = \frac{1}{\sigma_x D} \phi\left(\frac{x}{\sigma_x}\right) \forall x \in [-A, A], \quad (9)$$

where $D = \Phi(\frac{A}{\sigma_x}) - \Phi(-\frac{A}{\sigma_x})$, $\phi(\cdot)$ and $\Phi(\cdot)$ correspond to the PDF and the cumulative distribution function of the standard normal distribution, respectively. Unlike the uniform distribution, such an input distribution provides the flexibility of optimizing over its parameter σ_x^2 to achieve higher rates [11]. As in the previous section, one needs to evaluate the PDF of a generic random variable $T = X + N$ where $X \sim \mathcal{N}_A(0, \sigma_x^2)$ is a truncated Gaussian and N is an independent Gaussian random variable. After some derivations, one obtains

$$p_T(t) = g(t)w(t), \quad (10)$$

where $g(\cdot)$ and $w(\cdot)$ are given by:

$$g(t) = \frac{1}{\sqrt{2\pi(\sigma^2 + \sigma_x^2)}} \exp\left(-\frac{t^2}{2(\sigma^2 + \sigma_x^2)}\right) \quad (11)$$

$$w(t) = \frac{Q(\frac{-A-t\hat{\sigma}_x^2}{\hat{\sigma}}) - Q(\frac{A-t\hat{\sigma}_x^2}{\hat{\sigma}})}{D}. \quad (12)$$

An analytic expression for the optimal input variance σ_x^2 is difficult to obtain. However, based on numerical observations, σ_x^2 can be set to a simple heuristic value given by $\hat{\sigma}_x^2 = A^2$.

B. Lower and Upper bounds

Based on (7), the secret-key capacity can be lower bounded as follows

$$\begin{aligned} C_k &= \max_{p_X(x)} [\mathbb{I}(X, X + N_{eq}) - \mathbb{I}(X; Z)] \\ &\geq \max_{p_X(x)} \mathbb{I}(X, X + N_{eq}) - \max_{p_X(x)} \mathbb{I}(X; Z) \end{aligned} \quad (13)$$

$$= C_{BE} - C_E \triangleq C_{k,1}^{LB}, \quad (14)$$

where C_{BE} corresponds to the capacity of the enhanced receiver channel with input X and output $\frac{Y}{\sigma_D^2} + \frac{Z}{\sigma_E^2}$ and C_E corresponds to the capacity of the eavesdropper channel. Having closed-form expressions is of interest in many scenarios. Next, closed-form lower bounds are provided. Considering (7) and using [8, Theorem 1], the following lower bounds follow immediately

$$\begin{aligned} C_k &\geq \frac{1}{2} \log(1 + \frac{2A^2}{\pi e \sigma_{DE}^2}) - (1 - 2Q(\beta + \frac{A}{\sigma_E})) \log(\frac{2(\beta + \frac{A}{\sigma_E})}{\sqrt{2\pi}(1 - 2Q(\beta))}) \\ &\quad - Q(\beta) - \frac{\beta}{\sqrt{2\pi}} e^{-\frac{\beta^2}{2}} + \frac{1}{2} \triangleq C_{k,2}^{LB} \end{aligned} \quad (15)$$

$$C_k \geq \frac{1}{2} \log \frac{6 \frac{A^2}{\sigma_{DE}^2} + 3\pi e}{\pi e \frac{A^2}{\sigma_E^2} + 3\pi e} \triangleq C_{k,3}^{LB}, \quad (16)$$

where $\beta > 0$ is a free parameter. Since (15) holds true for any $\beta > 0$, one may maximize $C_{k,2}^{LB}$ over all β . Following [8, Theorem 1], (15) and (16) can be derived by using the dual expression for the secrecy capacity and choosing a particular distribution that results in a secrecy achievable rate.

Clearly, The secret-key capacity with an amplitude constraint A is upper bounded by the secret-key capacity with an average power constraint A^2 . It follows that

$$C_k \leq \frac{1}{2} \log(1 + \frac{A^2 \sigma_E^2}{(A^2 + \sigma_E^2) \sigma_D^2}) \triangleq C_k^{UB}. \quad (17)$$

C. Asymptotic analysis

First, the secret-key capacity is investigated for asymptotically high values of A .

Proposition 1. The secret-key capacity with amplitude constraint coincides with the secret-key capacity with an average power constraint and converges to $\frac{1}{2} \log(1 + \frac{\sigma_E^2}{\sigma_D^2})$ as A goes to infinity.

Proof: Setting $\beta = \log(1 + \frac{2A}{\sigma_E})$ as in [8], it can be seen that the upper bound C_k^{UB} and the lower bound $C_{k,2}^{LB}$ converge to the same value for asymptotically high values of A , given by $\frac{1}{2} \log(1 + \frac{\sigma_E^2}{\sigma_D^2})$. Thus, one obtains

$$\lim_{A \rightarrow \infty} C_k = \lim_{A \rightarrow \infty} C_{k,2}^{LB}(\beta^*) = \lim_{A \rightarrow \infty} C_k^{UB} = \frac{1}{2} \log(1 + \frac{\sigma_E^2}{\sigma_D^2}).$$

When A is very small, the behavior of the secret-key capacity is similar to the capacity in the absence of an eavesdropper.

Proposition 2. In the regime $\frac{A}{\sigma_{DE}} \ll 1$, the secret-key capacity behaves as the capacity of the legitimate user channel with no secrecy constraint as follows

$$\lim_{\frac{A}{\sigma_{DE}} \rightarrow 0} \frac{C_k}{\frac{1}{2} \frac{A^2}{\sigma_D^2}} = 1. \quad (18)$$

Proof: First, the asymptotic equivalent expression of the capacity for a Gaussian channel with no secrecy constraint is established. The result is summarized in the following lemma.

Lemma 2. Consider a Gaussian channel with amplitude constraint A with capacity C given by $Y = X + N$ such that $N \sim \mathcal{N}(0, \sigma^2)$. Then, it follows that

$$\lim_{\frac{A}{\sigma} \rightarrow 0} \frac{C}{\frac{1}{2} \frac{A^2}{\sigma^2}} = 1. \quad (19)$$

Proof: Without loss of generality, assume $\sigma = 1$. A lower bound of C is obtained by considering an equal pair of mass points at the interval extremes as a particular input distribution. The rate in this case is $R = h(Y) - \frac{1}{2} \log(2\pi e)$, where $h(Y)$ corresponds to the entropy of a mixed Gaussian distribution. From [12], $h(Y)$ is given by

$$h(Y) = \frac{1}{2} \log(2\pi e) + A^2 - I \quad (20)$$

$$I = \frac{2}{\sqrt{2\pi}A} \exp(-\frac{A^2}{2}) \int_0^\infty \exp(-\frac{y^2}{2A^2}) \cosh(y) \log(\cosh(y)) dy. \quad (21)$$

Then, it follows that $R = A^2 - I$. An upper bound of C is the capacity with average power constraint A^2 . On the other hand, we have $R \geq \frac{A^2}{2} - I$. It follows that

$$\frac{A^2}{2} - I \leq C \leq \frac{1}{2} \log(1 + A^2). \quad (22)$$

Clearly, one can write $\lim_{A \rightarrow 0} \frac{\frac{1}{2} \log(1 + \frac{A^2}{2})}{\frac{A^2}{2}} = 1$. Moreover, using the dominated convergence theorem, one can show that $\lim_{A \rightarrow 0} \frac{I}{\frac{A^2}{2}} = 0$. The result follows by noticing that the lower and upper bounds are equivalent to $\frac{A^2}{2}$ as $A \rightarrow 0$. See [13] for further details. ■

Going back to the proof of Proposition 2 and assuming $\frac{A}{\sigma_{DE}} \ll 1$, it follows that $\frac{A}{\sigma_E} \ll 1$ and $\frac{A}{\sigma_D} \ll 1$. Applying the result of Lemma 2 to (14), one obtains

$$\begin{aligned} \lim_{\frac{A}{\sigma_{DE}} \rightarrow 0} \frac{C_{k,1}^{LB}}{\frac{A^2}{2\sigma_D^2}} &= \frac{\sigma_D^2}{\sigma_{DE}^2} \lim_{\frac{A}{\sigma_{DE}} \rightarrow 0} (\frac{C_{BE}}{\frac{A^2}{2\sigma_D^2}}) - \frac{\sigma_D^2}{\sigma_E^2} \lim_{\frac{A}{\sigma_{DE}} \rightarrow 0} (\frac{C_E}{\frac{A^2}{2\sigma_D^2}}) \\ &= \frac{\sigma_D^2}{\sigma_{DE}^2} - \frac{\sigma_D^2}{\sigma_E^2} = 1. \end{aligned} \quad (23)$$

Moreover, from (17), one obtains

$$\lim_{\frac{A}{\sigma_{DE}} \rightarrow 0} \frac{C_k^{UB}}{\frac{A^2}{2\sigma_D^2}} = \lim_{\frac{A}{\sigma_{DE}} \rightarrow 0} \frac{\log(1 + \frac{A^2}{\sigma_D^2(1 + \frac{A^2}{\sigma_E^2})})}{\frac{A^2}{2\sigma_D^2}} = 1. \quad (24)$$

The result follows by combining (23) and (24). ■

V. NUMERICAL RESULTS

In this section, numerical results are presented to validate the analytical derivations. Figure 1 illustrates numerically the result in Theorem 1 by computing the secret-key capacity for $\sigma_D^2 = 1$ and $\sigma_E^2 = 2$. The secret-key capacity with an average power constraint A^2 , denoted C_k^{UB} , is also visualized. For comparison, Fig. 1 illustrates the secrecy capacity under an amplitude constraint C_s , the secrecy capacity under an average power constraint $C_s^{avg-cst}$, the lower bounds $C_{k,1}^{LB}$

Fig. 1. The secret-key and secrecy capacities versus the square of the peak amplitude constraint A .

Fig. 2. Secret-key rates for different schemes.

and $C_{k,3}^{LB}$ ($C_{k,2}^{LB}$ is negative over the considered range) and a lower bound to the secrecy capacity $C_m - C_e$, with C_m being the capacity of the legitimate receiver. It is observed that the rate of increase of C_k and $C_k^{avg-cst}$ are the same, which parallels the observations for the capacity with no secrecy constraint [4] and the secrecy capacity [9]. For low values of A , one observes that the secret-key capacity with an amplitude constraint coincides with its lower bound $C_{k,1}^{LB}$ and is very close the secret-key capacity with an average power constraint. Next, the performance of the proposed suboptimal schemes is illustrated in Fig. 2. The noise variances are set to $\sigma_D = 1$ and $\sigma_E = 1.5$. The maxentropic distribution coincides with the secret-key capacity for low values of A and achieves near capacity rates for higher values of A . Moreover, the heuristic choice of K behaves very close to the optimized maxentropic distribution. On the other hand, the continuous uniform distribution and the truncated Gaussian perform less efficiently for low values of A . However, for high values of A , the truncated Gaussian distribution (as well as the one with the heuristic choice of $\sigma_x = A$) outperforms all other suboptimal schemes and achieves rates very close to the capacity. Finally, Fig. 3 illustrates numerically the convergence of $C_{k,2}^{LB}(\beta^*)$ and C_k^{UB} to the same limit as A goes to infinity, which confirms the result in Proposition 1.

Fig. 3. The secret-key and secrecy capacities versus the square of the peak amplitude constraint A .

VI. CONCLUSION

In this paper, the capacity-achieving distribution of the channel model for secret-key agreement subject to a peak power constraint is proved to be discrete with finite number of probability mass points. To circumvent the numerical complexity associated with finding the optimal distribution, several schemes are proposed and shown numerically to perform close to the capacity. Moreover, upper and lower bounds to the secret-key capacity are provided and used to derive results about the behavior of the capacity in both asymptotic regimes of the amplitude constraint.
