Title: TRIPYRENE-BASED DIANHYDRIDES, POLYIMIDES, METHODS OF MAKING EACH, AND METHODS OF USE

Abstract: A triptycene-based monomer, a method of making a triptycene-based monomer, a triptycene-based aromatic polyimide, a method of making a triptycene-based aromatic polyimide, methods of using triptycene-based aromatic polyimides, structures incorporating triptycene-based aromatic polyimides, and methods of gas separation are provided. Embodiments of the triptycene-based monomers and triptycene-based aromatic polyimides have high permeabilities and excellent selectivities. Embodiments of the triptycene-based aromatic polyimides have one or more of the following characteristics: intrinsic microporosity, good thermal stability, and enhanced solubility. In an exemplary embodiment, the triptycene-based aromatic polyimides can be used to form a gas separation membrane.
TRIPTYCENE-BASED DIANHYDRIDES, POLYIMIDES, METHODS OF MAKING EACH, AND METHODS OF USE

BACKGROUND

Gas separation is an emerging technology with a rapidly developing market comprising applications like air separation for oxygen or nitrogen enrichment as well as acid gas removal and hydrocarbon recovery from natural gas streams. The economics of a membrane-based separation system depend on the gas permeability (thickness- and pressure-normalized flux) and selectivity (preferential permeation of one gas over another) of the material used. Unfortunately, there is a conventional trade-off between these two main parameters such that an increase in permeability is concurrent with a decrease in selectivity, and vice versa. This results in what is commonly referred to as an “upper-bound” to performance which is defined by polymeric materials with the highest known combinations of permeability and selectivity. It is revised to accommodate discoveries of better performing polymers and is therefore taken as a gauge of the state-of-the-art.

Polyimides are one dominant class of polymers developed by major competitors in the membrane-based gas separation industry for a range of gas separation applications including air separations (oxygen/nitrogen enrichment) and hydrogen separations (hydrogen recovery from ammonia purge-gas streams) as well as the removal of acid gases (CO₂ and H₂S) and higher hydrocarbons (C₂+) from natural gas. Polyimides, typically formed by the polycondensation reaction between a diamine and dianhydride followed by the cyclodehydration step, have a versatile structure amenable to simple, systematic changes. They are well known as high performance polymers which possess high thermal and chemical stabilities, good mechanical and superior film-forming properties. However, current polyimides do not address current gas separation needs, and therefore, new polyimides are desirable.

Discussion

Before the present disclosure is described in greater detail, it is to be understood that this disclosure is not limited to particular embodiments
described, as such may, of course, vary. It is also to be understood that the
terminology used herein is for the purpose of describing particular
embodiments only, and is not intended to be limiting, since the scope of the
present disclosure will be limited only by the appended claims.

Where a range of values is provided, it is understood that each
intervening value, to the tenth of the unit of the lower limit (unless the context
clearly dictates otherwise), between the upper and lower limit of that range,
and any other stated or intervening value in that stated range, is
encompassed within the disclosure. The upper and lower limits of these
smaller ranges may independently be included in the smaller ranges and are
also encompassed within the disclosure, subject to any specifically excluded
limit in the stated range. Where the stated range includes one or both of the
limits, ranges excluding either or both of those included limits are also
included in the disclosure.

Unless defined otherwise, all technical and scientific terms used herein
have the same meaning as commonly understood by one of ordinary skill in
the art to which this disclosure belongs. Although any methods and materials
similar or equivalent to those described herein can also be used in the
practice or testing of the present disclosure, the preferred methods and
materials are now described.

All publications and patents cited in this specification are herein
incorporated by reference as if each individual publication or patent were
specifically and individually indicated to be incorporated by reference and are
incorporated herein by reference to disclose and describe the methods and/or
materials in connection with which the publications are cited. The citation of
any publication is for its disclosure prior to the filing date and should not be
construed as an admission that the present disclosure is not entitled to
antedate such publication by virtue of prior disclosure. Further, the dates of
publication provided could be different from the actual publication dates that
may need to be independently confirmed.

As will be apparent to those of skill in the art upon reading this
disclosure, each of the individual embodiments described and illustrated
herein has discrete components and features which may be readily separated
from or combined with the features of any of the other several embodiments
without departing from the scope or spirit of the present disclosure. Any recited method can be carried out in the order of events recited or in any other order that is logically possible.

Embodiments of the present disclosure will employ, unless otherwise indicated, techniques of chemistry, synthetic organic chemistry, polymer chemistry, analytical chemistry, and the like, which are within the skill of the art. Such techniques are explained fully in the literature.

The following examples are put forth so as to provide those of ordinary skill in the art with a complete disclosure and description of how to perform the methods and use the compositions and compounds disclosed and claimed herein. Efforts have been made to ensure accuracy with respect to numbers (e.g., amounts, temperature, etc.), but some errors and deviations should be accounted for. Unless indicated otherwise, parts are parts by weight, temperature is in °C, and pressure is in bar. Standard temperature and pressure are defined as 0 °C and 1 bar.

Before the embodiments of the present disclosure are described in detail, it is to be understood that, unless otherwise indicated, the present disclosure is not limited to particular materials, reagents, reaction materials, manufacturing processes, or the like, as such can vary. It is also to be understood that the terminology used herein is for purposes of describing particular embodiments only, and is not intended to be limiting. It is also possible in the present disclosure that steps can be executed in different sequence where this is logically possible.

It must be noted that, as used in the specification and the appended claims, the singular forms "a," "an," and "the" include plural referents unless the context clearly dictates otherwise. Thus, for example, reference to "a support" includes a plurality of supports. In this specification and in the claims that follow, reference will be made to a number of terms that shall be defined to have the following meanings unless a contrary intention is apparent.

Definitions:

The term "substituted" refers to any one or more hydrogens on the designated atom that can be replaced with a selection from the indicated group, provided that the designated atom's normal valence is not exceeded.
and that the substitution results in a stable compound.

As used herein, "alkyl" or "alkyl group" refers to a branched saturated aliphatic hydrocarbon. Examples of alkyl include, but are not limited to isopropyl, sec-butyl, t-butyl, and iso-pentyl.

The term "substituted," as in "substituted alkyl," "substituted aryl," "substituted heteroaryl" and the like means that the substituted group may contain in place of one or more hydrogens a group such as alkyl, hydroxy, amino, halo, trifluoromethyl, cyano, --NH(lower alkyl), --N(lower alkyl)$_2$, lower alkoxy, lower alkylthio, or carboxy, and thus embraces the terms haloalkyl, alkoxy, fluorobenzyl, and the sulfur and phosphorous containing substitutions referred to below.

As used herein, "halo", "halogen", or "halogen radical" refers to a fluorine, chlorine, bromine, and iodine, and radicals thereof. Further, when used in compound words, such as "haloalkyl" or "haloalkenyl", "halo" refers to an alkyl or alkenyl radical in which one or more hydrogens are substituted by halogen radicals. Examples of haloalkyl include, but are not limited to, trifluoromethyl, trichloromethyl, pentafluoroethyl, and pentachloroethyl.

The term "aryl" as used herein, refers to an aromatic monocyclic or multicyclic ring system of about 6 to about 14 carbon atoms, preferably of about 6 to about 10 carbon atoms. Exemplary aryl groups include phenyl or naphthyl, or phenyl substituted or naphthyl substituted.

The term "heteroaryl" is used herein to denote an aromatic ring or fused ring structure of carbon atoms with one or more non-carbon atoms, such as oxygen, nitrogen, and sulfur, in the ring or in one or more of the rings in fused ring structures. Preferred examples are furanyl, imidazyl, pyranyl, pyrrolyl, and pyridyl.

**General Discussion**

Embellishments of the present disclosure provide for a triptycene-based monomer, a method of making a triptycene-based monomer, a triptycene-based aromatic polyimide, a method of making a triptycene-based aromatic polyimide, methods of using triptycene-based aromatic polyimides, structures incorporating triptycene-based aromatic polyimides, methods of gas
separation, and the like. Embodiments of the triptycene-based aromatic polyimides have one or more of the following characteristics: intrinsic microporosity, good thermal stability, and enhanced solubility. Intrinsic microporosity is defined herein as a polymeric material with pore sizes of less than 2 nm and a surface porosity of > 100 m²/g, as determined by nitrogen adsorption method at 77 K. Attachment A includes exemplary reactions schemes and gas separation data for an embodiment of a triptycene-based aromatic polyimide.

Embodiments of the triptycene-based monomers and triptycene-based aromatic polyimides are expected to be economically attractive compared with the current polymer-based membranes due to their high permeabilities and excellent selectivities. Higher permeability offers savings in capital cost of membrane systems by reducing area requirements to handle a given process flow. It also reduces energy consumption by reducing compression requirements. Higher selectivity introduces large savings by reducing crossover of valuable gas feed components into the permeate streams and also by reducing the need for multi-stage systems.

In an exemplary embodiment, a triptycene-based aromatic polyimide can be used to form a gas separation membrane. The membrane can have exceptional performance for gas separation applications significantly transcending the upper bounds. Specifically, embodiments of membranes incorporating the triptycene-based polyimide provide unprecedented performance in gas separation applications including nitrogen enrichment and hydrogen recovery from ammonia purge-gas streams. In addition, embodiments of membranes incorporating the triptycene-based polyimide have excellent performance in olefin/paraffin (C₃H₆/C₃H₈) and natural gas sweetening (CO₂/CH₄) applications.

In an exemplary embodiment, triptycene-based aromatic polyimides are microporous and have the highest BET surface area (e.g., up to 850 m²/g) of all previously reported non-network polyimides, as conventionally measured by the area accessible to N₂ molecules at 77K. The microporosity and the good solubility (processability) of these materials appears to have resulted from the incorporation of the rigid three-dimensional structure of a triptycene moiety, which prevents the close packing of the polymer chains and
decreases the interchain interactions. Embodiments of these polyimides demonstrate performance significantly transcending the upper-bounds for important gas separation applications. In particular, exemplary embodiments of the triptycene-based aromatic polyimides when used in gas separation membranes demonstrate unprecedented combinations of permeability and selectivity in air separations (i.e., O₂/N₂ in nitrogen enrichment), hydrogen separations (i.e., H₂/N₂ and H₂/CH₄ for hydrogen recovery from ammonia purge gas streams), and challenging olefin/paraffin separations (i.e., C₃H₆/C₃H₈). Furthermore, these materials show excellent performance relative to the upper-bound for CO₂/CH₄ separations (natural gas sweetening). Attachment A includes data that describes the gas separation properties of membranes made from the triptycene-based aromatic polyimide of the present disclosure.

In addition, due to their good solubilities, thermal and chemical stabilities, and high microporosities, these materials can be implemented in a wide range of industrial applications related to thermally stable coatings, low dielectric constant films, optoelectronic materials, sensors, and gas storage media.

In an exemplary embodiment, the triptycene-based aromatic polyimide can be made using a triptycene-based monomer as shown in the following structure:

In an embodiment, AR can be a substituted or un-substituted aromatic moiety. In an exemplary embodiment, the substituted or un-substituted aromatic moiety can be: a substituted or un-substituted aryl group, a substituted or un-substituted heteroaryl group. In an embodiment, AR can be one of the groups shown in Scheme 2.
In an embodiment, R1 and R2 can each independently be hydrogen or a substituted or non-substituted alkyl group. In particular, R1 and R2 can each be independently substituted or un-substituted branched C3 to C5 alkyl groups.

Representative triptycene-based monomers can have the following structures:

In an exemplary embodiment, the triptycene-based monomer can be synthesized using the synthesis described in Scheme 1 in Attachment A. Although some specific solvents, acids, and other reagents are described, other suitable solvent, acids, and reagents can be used if they accomplish the same purpose. R can include the same groups as R1 and R2.

In an exemplary embodiment, the triptycene-based aromatic polyimide can include a compound as represented by the following structure:
In an embodiment, n can be 1 to 10,000. In an exemplary embodiment, X can be a triptycene-based monomer as described above. In an exemplary embodiment, Y can be a divalent organic group. In an embodiment, Y can be represented by AR', where AR' can be a group as described in Scheme 2, Attachment A. AR' corresponds to the base of various diamines that can be used to form the polyimide. In an embodiment, the divalent organic group is selected from the group consisting of: a substituted or un-substituted aryl group, a substituted or un-substituted heteroaryl group.

Representative triptycene-based aromatic polyimides can have the following structures:
In an exemplary embodiment, the triptycene-based aromatic polyimide can be synthesized by reacting the triptycene-based monomer with a multi-amine. In an embodiment, the multi-amine can include a diamine, triamine, tetramine, and an amine having 5 or more amino groups.

An exemplary embodiment of a synthesis can include the reaction scheme shown below:
AR, R1, and R2 have the same meaning as described above. DA is a linking group derived from the diamine. In an embodiment, the diamine can include those described in Schemes 2 and 3. In an embodiment, DA can include AR', as described in Scheme 2.

In another embodiment, the triptycene-based aromatic polyimide can be synthesized by reacting the triptycene-based monomer with a triamine or multi-amine. In this embodiment, an insoluble microporous network of polyimides can be formed that can be used for gas storage (e.g., H₂, CO₂, CH₄, and the like). An exemplary reaction scheme is shown in Scheme 5.

In another embodiment, a polypyrrolone can be synthesized by reacting the triptycene-based monomer with a multi-amine. An exemplary reaction scheme is shown in Scheme 4.

As mentioned above, polyimides of the present disclosure can be used to form membranes that can be used in gas separation. The membranes including the polyimides can be formed using conventional techniques.

As mentioned above, the membranes of the present disclosure can be used in conventional gas separation systems such as systems to enrich a specific gas content in a gas mixture (e.g., oxygen enrichment, nitrogen enrichment, and the like). In addition, the membranes can be used in hydrogen gas separations.
In general, a first gas is separated from a first gas mixture with a membrane of the present disclosure to form a second gas mixture that is enriched in one or more components of the first gas mixture. In an embodiment, the result can be the separation of a gas(es) from another gas(es) such as in oxygen/nitrogen, hydrogen/methane, hydrogen/nitrogen, carbon dioxide/methane, carbon dioxide/nitrogen, hydrogen/C_{2}+ hydrocarbons, hydrogen sulfide/methane, carbon dioxide/hydrogen sulfide, ethylene/ethane, propylene/propane, water vapor/hydrocarbons, C_{2}+/hydrogen, C_{2}+/methane etc.

EXAMPLES

Now having described the embodiments of the disclosure, in general, the examples describe some additional embodiments. While embodiments of the present disclosure are described in connection with the example and the corresponding text and figures, there is no intent to limit embodiments of the disclosure to these descriptions. On the contrary, the intent is to cover all alternatives, modifications, and equivalents included within the spirit and scope of embodiments of the present disclosure.

Example 1

See Attachment A

It should be noted that ratios, concentrations, amounts, and other numerical data may be expressed herein in a range format. It is to be understood that such a range format is used for convenience and brevity, and thus, should be interpreted in a flexible manner to include not only the numerical values explicitly recited as the limits of the range, but also to include all the individual numerical values or sub-ranges encompassed within that range as if each numerical value and sub-range is explicitly recited. To illustrate, a concentration range of “about 0.1% to about 5%” should be interpreted to include not only the explicitly recited concentration of about 0.1 wt% to about 5 wt%, but also include individual concentrations (e.g., 1%, 2%, 3%, and 4%) and the sub-ranges (e.g., 0.5%, 1.1%, 2.2%, 3.3%, and 4.4%) within the indicated range. In an embodiment, the term “about” can include
traditional rounding according to significant figures of the numerical value. In
addition, the phrase "about 'x' to 'y'" includes "about 'x' to about 'y'."

It should be emphasized that the above-described embodiments of the
present disclosure are merely possible examples of implementations, and are
set forth only for a clear understanding of the principles of the disclosure.
Many variations and modifications may be made to the above-described
embodiments of the disclosure without departing substantially from the spirit
and principles of the disclosure. All such modifications and variations are
intended to be included herein within the scope of this disclosure.

\( \text{Ar} = \) ![Image of a benzen ring]

Scheme (3): Other Diamines for the Synthesis of Novel Polyimides
Other Potential Applications of the Prepared Polyimides

Due to their good solubilities, thermal and chemical stabilities, and high microporosities, these materials are potentially implementable in a wide range
of important industrial applications related to thermally stable coatings, low dielectric constant films, optoelectronic materials, sensors and gas storage media.

**Other Classes of Materials Derivable From These Novel Dianhydrides**

Other interesting polymers which can also be prepared from these novel dianhydride monomers are polypyrrolones. These materials possess more rigidity than polyimides and thus can be more efficient molecular sieves. Polypyrrolones are generally prepared by the polycondensation reaction of a dianhydride monomer and a tetra-amine monomer as displayed in the following scheme:

![Polymerization Scheme](image)

1. Suitable solvent (DMAC, NMP,...)
2. Thermal treatment

The dianhydrides can also react with triamine or multi-amines to produce insoluble microporous network polyimides for other applications, such as H₂, CO₂ and CH₄ storage, as shown below.
Gas Transport Testing Method

The gas permeability of the membranes was determined using the constant-volume/variable-pressure method. The membranes were degassed in the permeation test apparatus on both sides under high vacuum at 35 °C for at least 24 h. The increase in permeate pressure with time was measured by a MKS Baratron transducer (range from 0 to 10 torr). The permeability of all gases was measured at 2 bar and 35 °C and was calculated by

\[ P = 10^{10} \frac{V_d}{p_{up} T R A} \frac{dP}{dt} \]

where \( P \) is the permeability (Barrers) \( (1 \text{ Barrer} = 10^{-10} \text{ cm}^3 \text{(STP)} \text{ cm} / \text{(cm}^2 \text{ s cmHg} \)) \), \( p_{up} \) is the upstream pressure (cmHg), \( dP/dt \) is the steady-state permeate-side pressure increase (cmHg/s), \( V_d \) is the calibrated permeate volume (cm\(^3\)), \( l \) is the membrane thickness (cm), \( A \) is the effective membrane area (cm\(^2\)), \( T \) is the operating temperature (K), and \( R \) is the gas constant \( (0.278 \text{ cm}^3 \text{ cmHg} / \text{(cm}^3 \text{ (STP) K}) \)) . The pure-gas selectivity of gas A over gas B was calculated by the ratio of their permeabilities

\[ \alpha_A^B = \frac{P_A}{P_B} \]

Following is a tabulation of gas transport properties for the prepared polyimides specified in **Scheme (2)**. The polymer naming is as such: TPDA-#, where TPDA refers to the 9,10-disopropyl dianhydride, and # refers to the diamine used as per the numbering shown in **Scheme (2)**.

All data was collected at 2 bar feed pressure and 35 °C using the constant-volume/variable-pressure technique.
Minor Change to Original Plots (Labeling)

Below, the original plots were modified to accommodate a change in the PIM-PI-TRIP label to TPDA-1 for consistency with the tabulations above.
CLAIMS

We claim at least the following:

1. A composition, comprising:
   a triptycene-based aromatic polyimide having the following structure:
   ![N-C-X-N-Y]_n
   wherein n is 1 to 10,000, wherein X is:
   ![AR-R1-R2]
   wherein Y is a divalent organic group, wherein AR is a substituted or un-substituted aromatic moiety, wherein R1 is a substituted or un-substituted branched alkyl group, wherein R2 is hydrogen, a substituted or un-substituted alkyl group, substituted or un-substituted branched alkyl group, or substituted or un-substituted phenyl group.

2. The composition of claim 1, wherein the divalent organic group is selected from the group consisting of: aromatic diamine, aromatic triamine, and aromatic tetramine.

3. The composition of claim 1, wherein the substituted or un-substituted aromatic moiety is selected from the group consisting of: phenyl and naphthyl.
4. The composition of claim 1, wherein substituted or un-substituted R1 and R2 are independently is selected from the group consisting of: substituted or un-substituted branched C3 to C5 alkyl groups.

5. The composition of claim 1, wherein AR is a group as shown in Scheme 2.

6. The composition of claim 1, wherein Y is AR', and AR' is a group as shown in Scheme 2.

7. A composition, comprising a monomer as shown in the following structure:

![Chemical Structure](image)

wherein AR is a substituted or un-substituted aromatic moiety, wherein R1 is hydrogen or a substituted or un-substituted branched alkyl group, and wherein R2 is hydrogen, or a substituted or un-substituted alkyl group, substituted or un-substituted branched alkyl group, or substituted or un-substituted phenyl group.

8. The composition of claim 7, wherein AR is a group as shown in Scheme 2.

9. The composition of claim 7, wherein the substituted or un-substituted aromatic moiety is selected from the group consisting of: phenyl and naphthyl.

10. The composition of claim 7, wherein substituted or un-substituted R1 and R2 are independently is selected from the group consisting of: substituted or un-substituted branched C3 to C5 alkyl groups.
11. A method of making a dianhydride, comprising:

\[ \text{isoamyl nitrite, HCl, 0}^\circ\text{C} \]

\[ \text{BBr}_3 \]

\[ \text{K}_2\text{CO}_3, \text{DMF, heat} \]

1. KOH, heat
2. Acetic anhydride, reflux

\[ \text{Ar} \]

\[ \text{R}_1, \text{R}_2 \]
wherein AR is a substituted or un-substituted aromatic moiety, wherein R1, R2, and R are each independently selected from: wherein R1 is substituted or un-substituted branched alkyl group, and wherein R2 is hydrogen, a substituted or un-substituted alkyl group, substituted or un-substituted branched alkyl group, or substituted or un-substituted phenyl group.

12. The composition of claim 11, wherein AR is a group as shown in Scheme 2.

13. The composition of claim 11, wherein the substituted or un-substituted aromatic moiety is selected from the group consisting of: phenyl and naphthyl.

14. The composition of claim 11, wherein substituted or un-substituted R, R1, and R2 are each independently is selected from the group consisting of: substituted or un-substituted branched C3 to C5 alkyl groups.

15. A method for making a polyimide, comprising: reacting a monomer of claim 7 with a multi-amine to form a polyimide.

16. The method of claim 15, wherein the multi-amine is selected from the group consisting of a diamine, triamine, tetramine, and an amine having 5 or more amino groups.

17. The method of claim 15, wherein the reaction scheme is as follows:
wherein AR is a substituted or un-substituted aromatic moiety, wherein R1 is substituted or un-substituted branched alkyl group, and R2 is hydrogen, a substituted or un-substituted alkyl group, substituted or un-substituted branched alkyl group, or substituted or un-substituted phenyl group, and DA is a linking group derived from the diamine.

18. The method of claim 17, wherein the diamine includes those described in Schemes 2 and 3.

19. The method of claim 18, wherein the DA is derived from one of the diamines described in Schemes 2 and 3.

20. A method for making a polyimide, comprising: reacting a monomer of claim 7 with a multi-amine to form a polypyrrolone.

21. The method of claim 20, wherein the reaction scheme is as follows:
wherein each AR is independently selected.

23. A method of separating a gas from a gas mixture, comprising: separating a first gas from a first gas mixture with a membrane of claim 22 to form a second gas mixture.

24. The method of claim 23, wherein the first gas is selected from the group consisting of: He, H₂, CO₂, H₂S, O₂, N₂, CH₄, saturated C₂+ hydrocarbons, C₂H₄, C₂H₆, C₃H₆, C₃H₈ and a combination thereof.

25. The method of claim 23, wherein the second gas mixture is oxygen enriched when compared to the first gas mixture.

26. The method of claim 23, wherein the second gas mixture is nitrogen enriched when compared to the first gas mixture.
